

Chapter 4

In-depth study of Middleware Architectures

E.g. COM/DCOM, CORBA, .NET

Outline

- What is Middleware
- Usage/Advantages
- Architectural Significance
- Middleware Types
- Advantages and Disadvantages of Middleware

Middleware - Definition

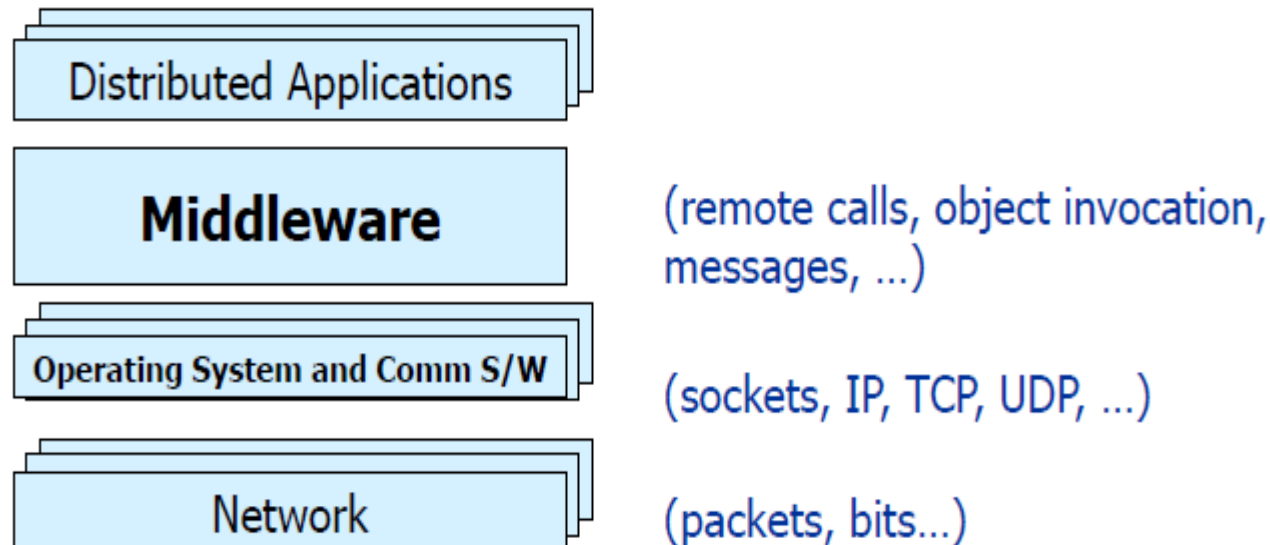

- **Middleware** is **connectivity software** that consists of a set of enabling services that **allow multiple processes running on one or more machines to interact with each other**.
- **Middleware** is the "**glue**" that **connects diverse computer systems**. Typically, **legacy systems store information in proprietary formats**, use proprietary protocols to communicate, and may even be running on hardware that's no longer manufactured or supported.

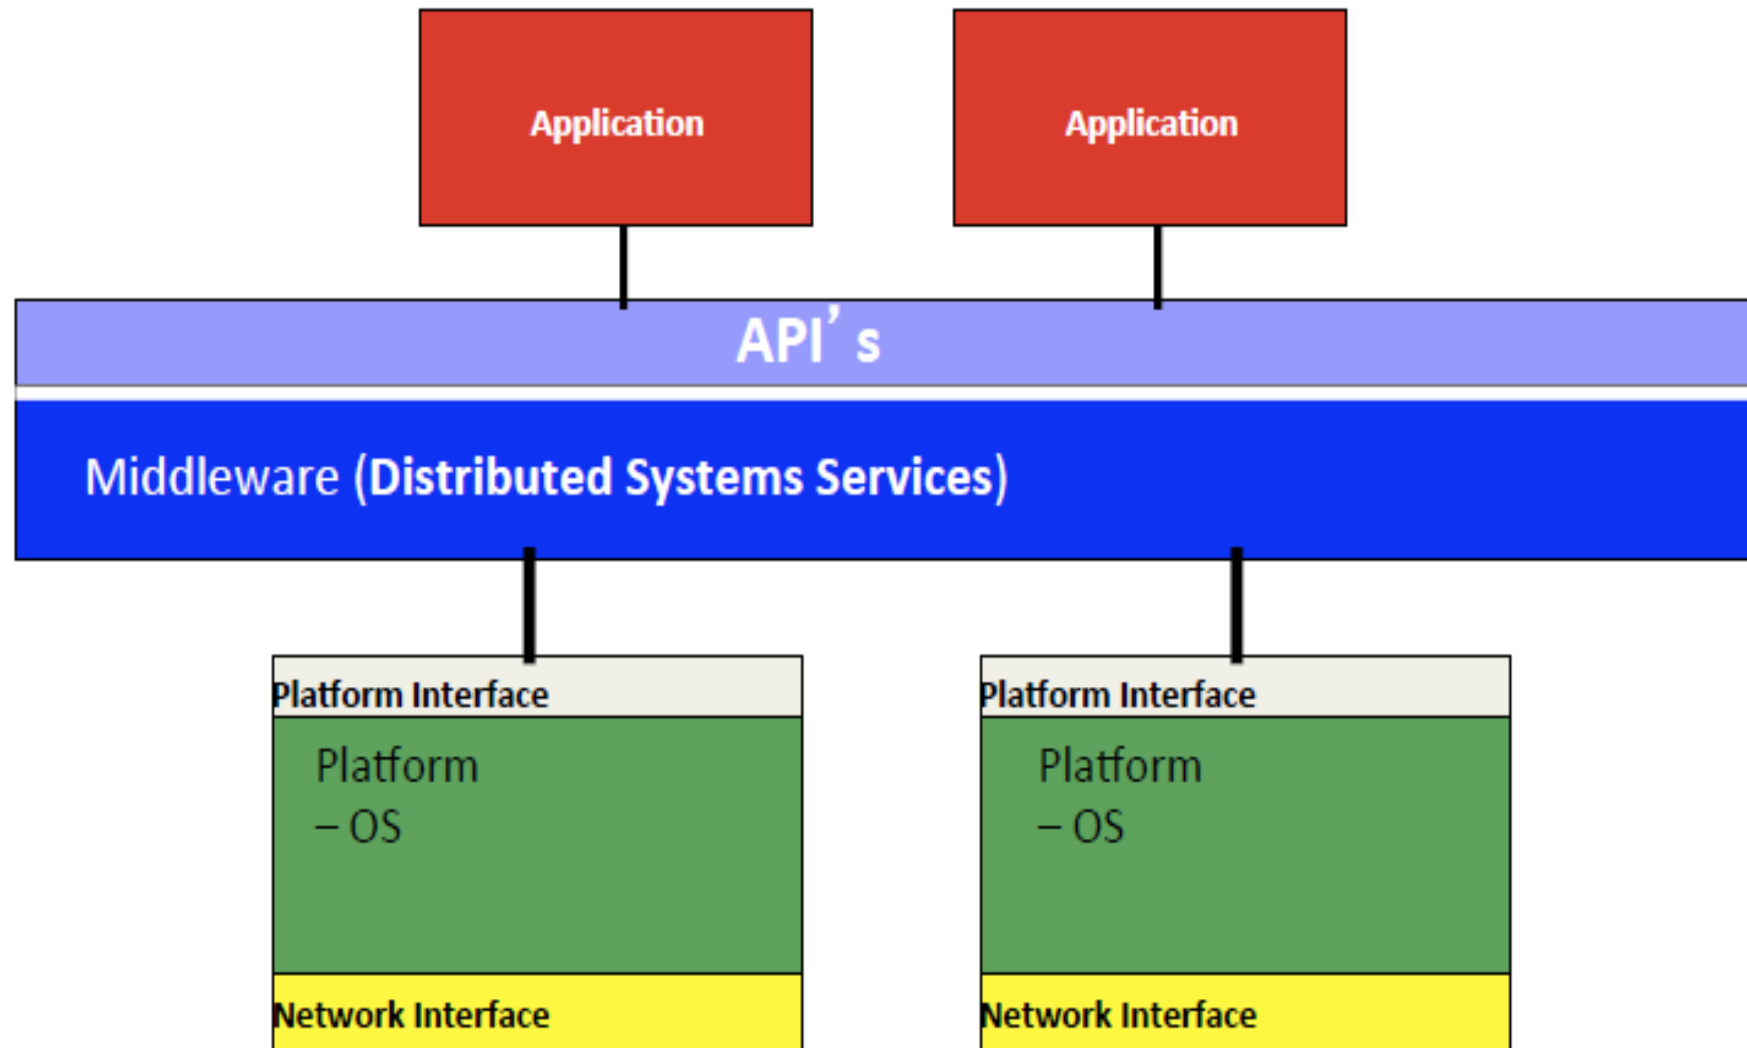

Middleware

- What is Middleware?

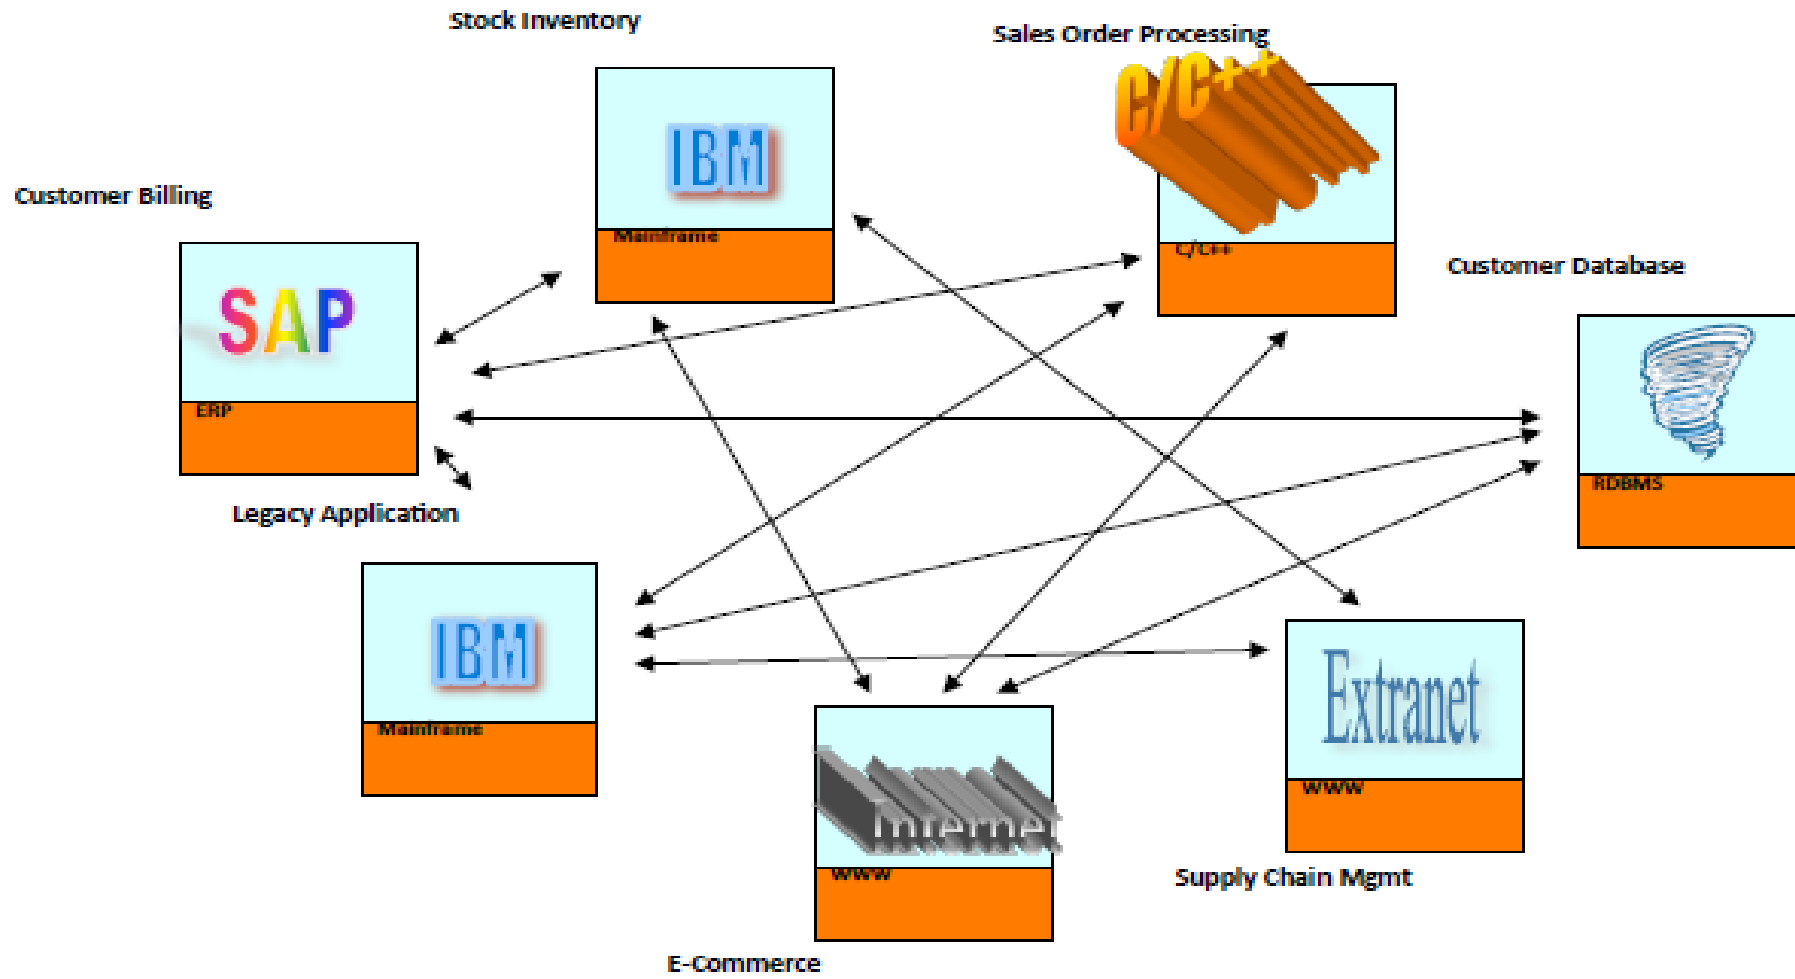

- Layer between **OS** and **distributed applications**
- Hides complexity and heterogeneity of distributed system
- Bridges gap between low-level OS communications and programming language abstractions
- Provides common programming abstraction and infrastructure for distributed applications

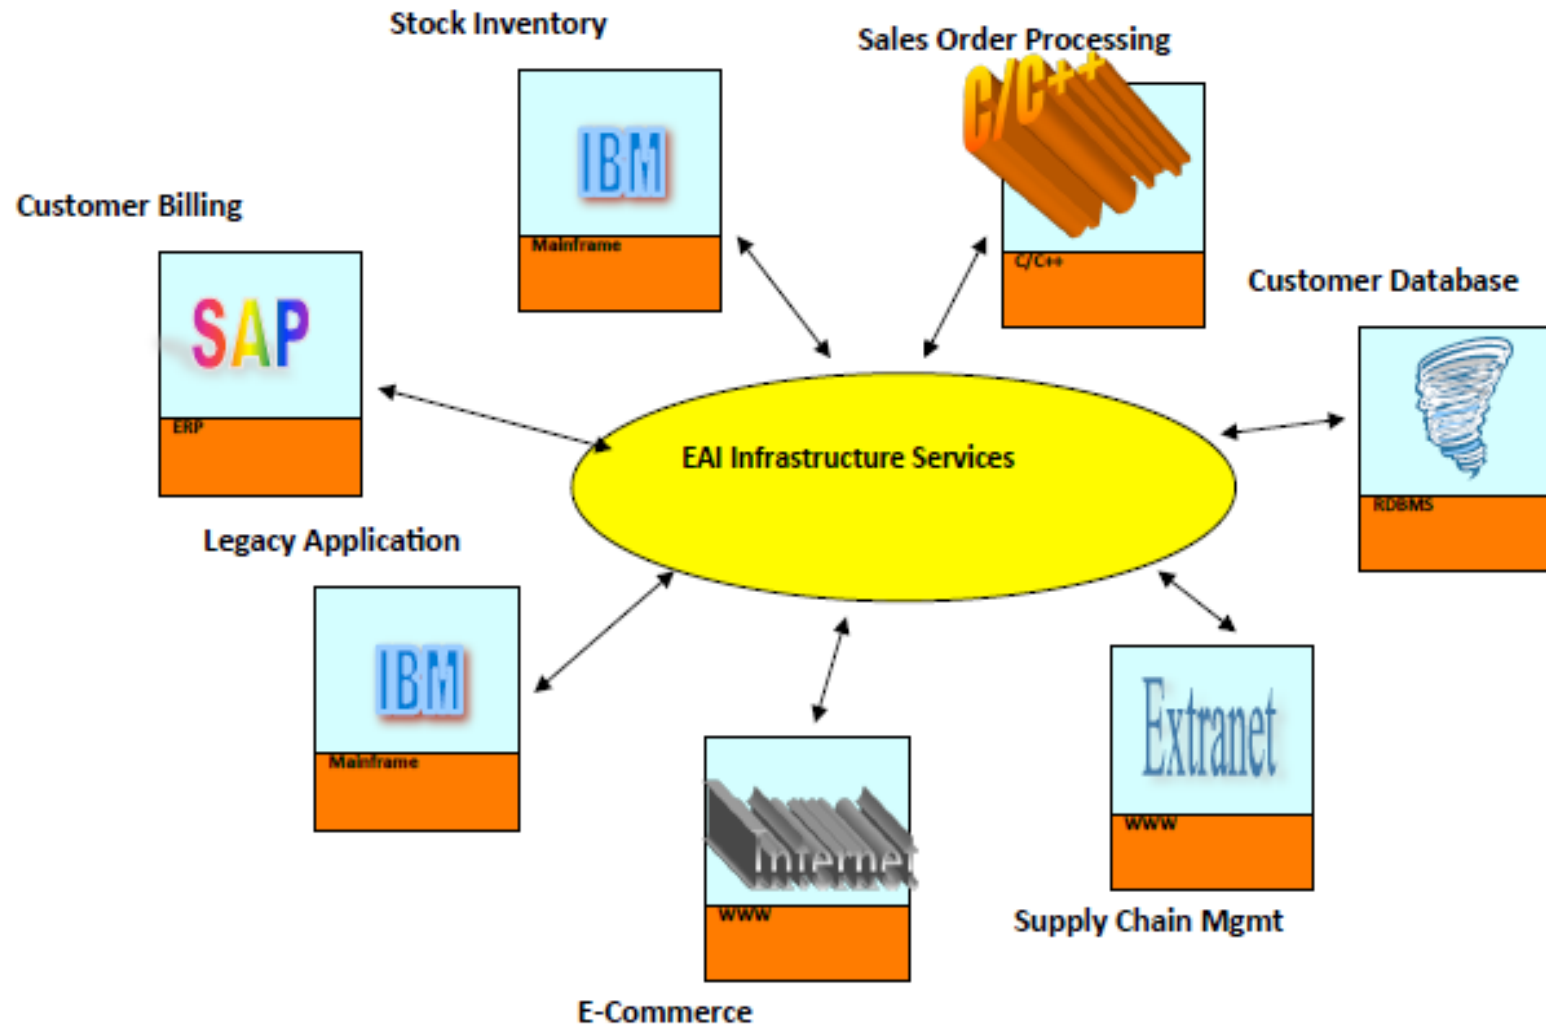

Middleware Architecture

Legacy enterprise situation

Middleware solution

Middleware - Usage

- Middleware services provide a more functional set of API than OS and network services to allow an application to:
 - Locate transparently across the network, providing interaction with other application or service
 - Be independent from network services.
 - Be reliable and available.
 - Scale-up in capacity without losing functionality.
 - Real time information access among systems
 - Streamlines business processes and helps raise organizational efficiency.
 - Maintains information integrity across multiple systems .

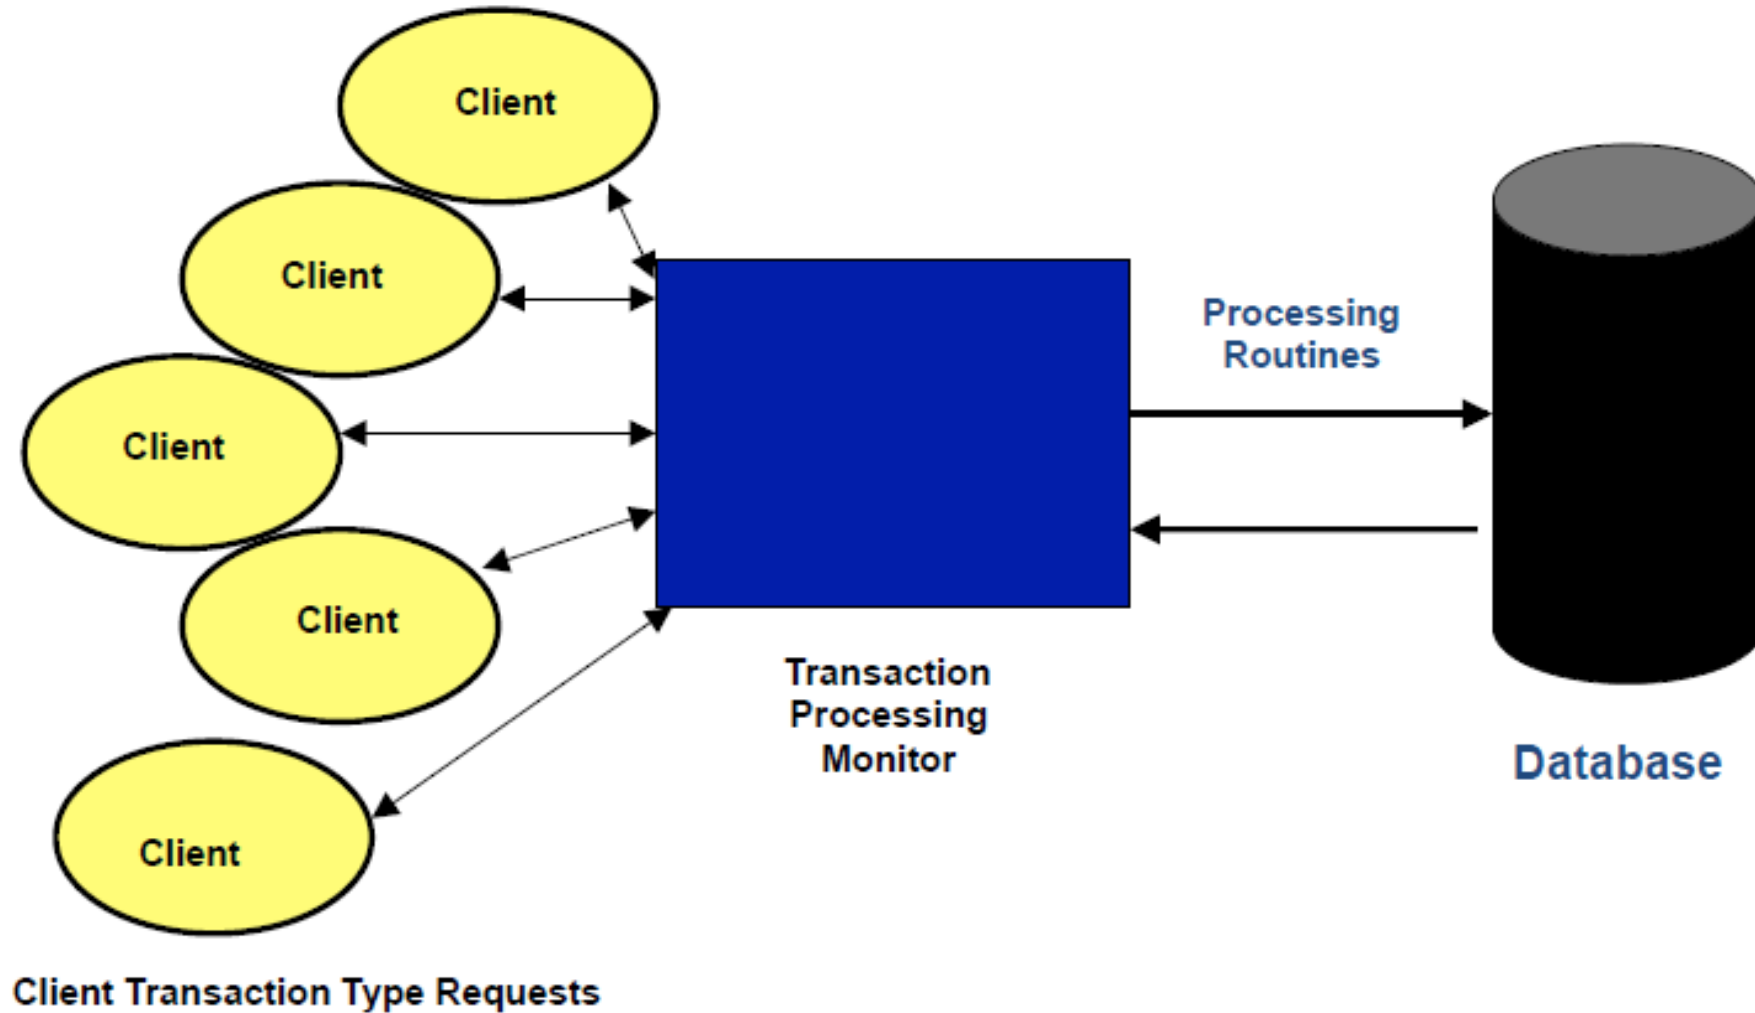

Disadvantages of Middleware

- Prohibitively high development costs.
- **EAI**(Enterprise Application Integration) implementations are very time consuming, and need a lot of resources.
- There are few people with experience in the market place.
- There exists relatively few satisfying standards.
- The tools are not good enough.
- Too many platforms to be covered.
- Middleware often threatens the real-time performance of a system.
- Middleware products are not very mature.

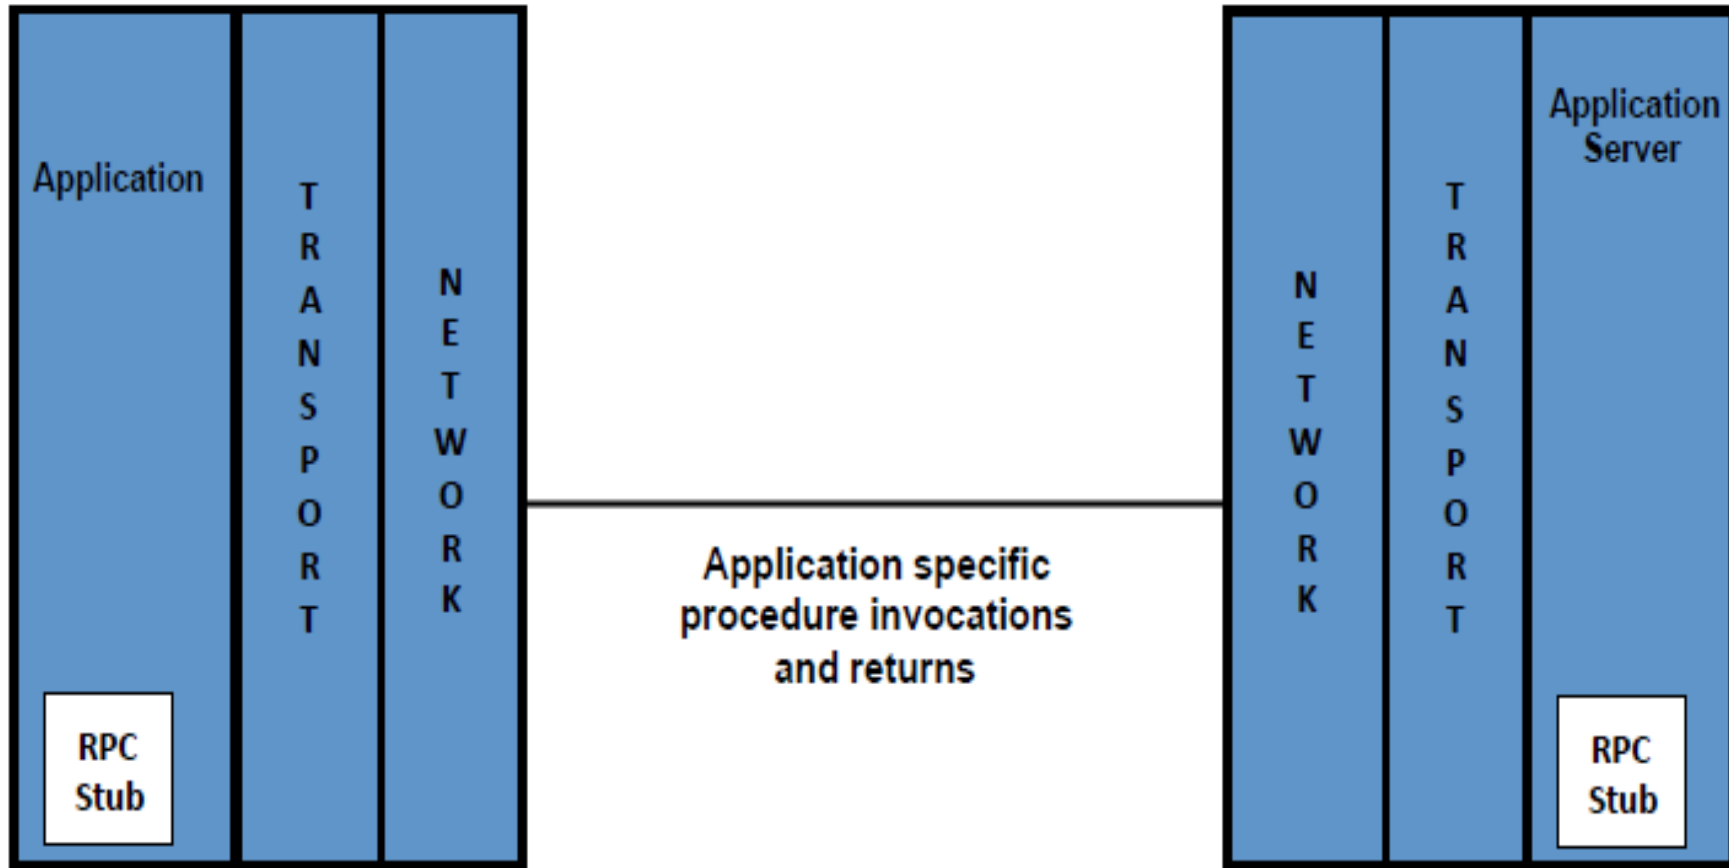

Middleware Evolutions

- Transaction Processing (TP) monitors
- Remote Procedure Calls (RPC)
- Message Oriented Middleware (MOM)
- Object Request Brokers (ORBs)
- Service oriented Architecture(SOA)

TP Monitors - Demonstration

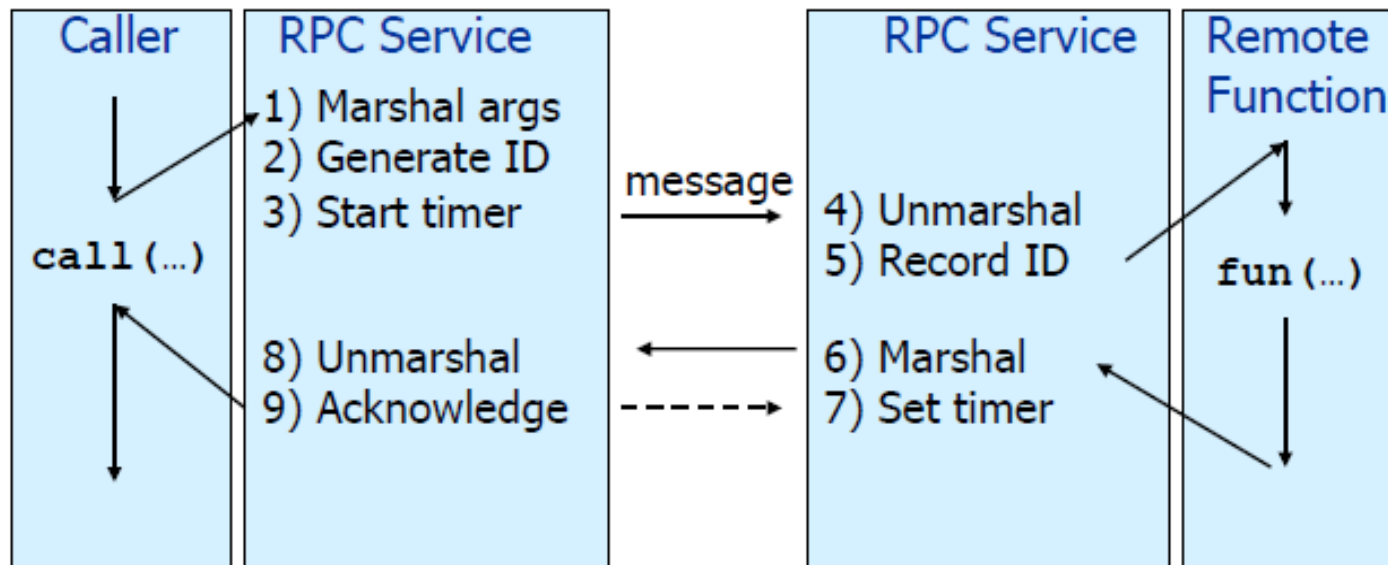

Remote Procedure Call (RPC)

Remote Procedure Call (RPC)

- Masks remote function calls as being local
- Client/server model
- Request/reply paradigm usually implemented with message passing in RPC service
- Marshalling of function parameters and return value

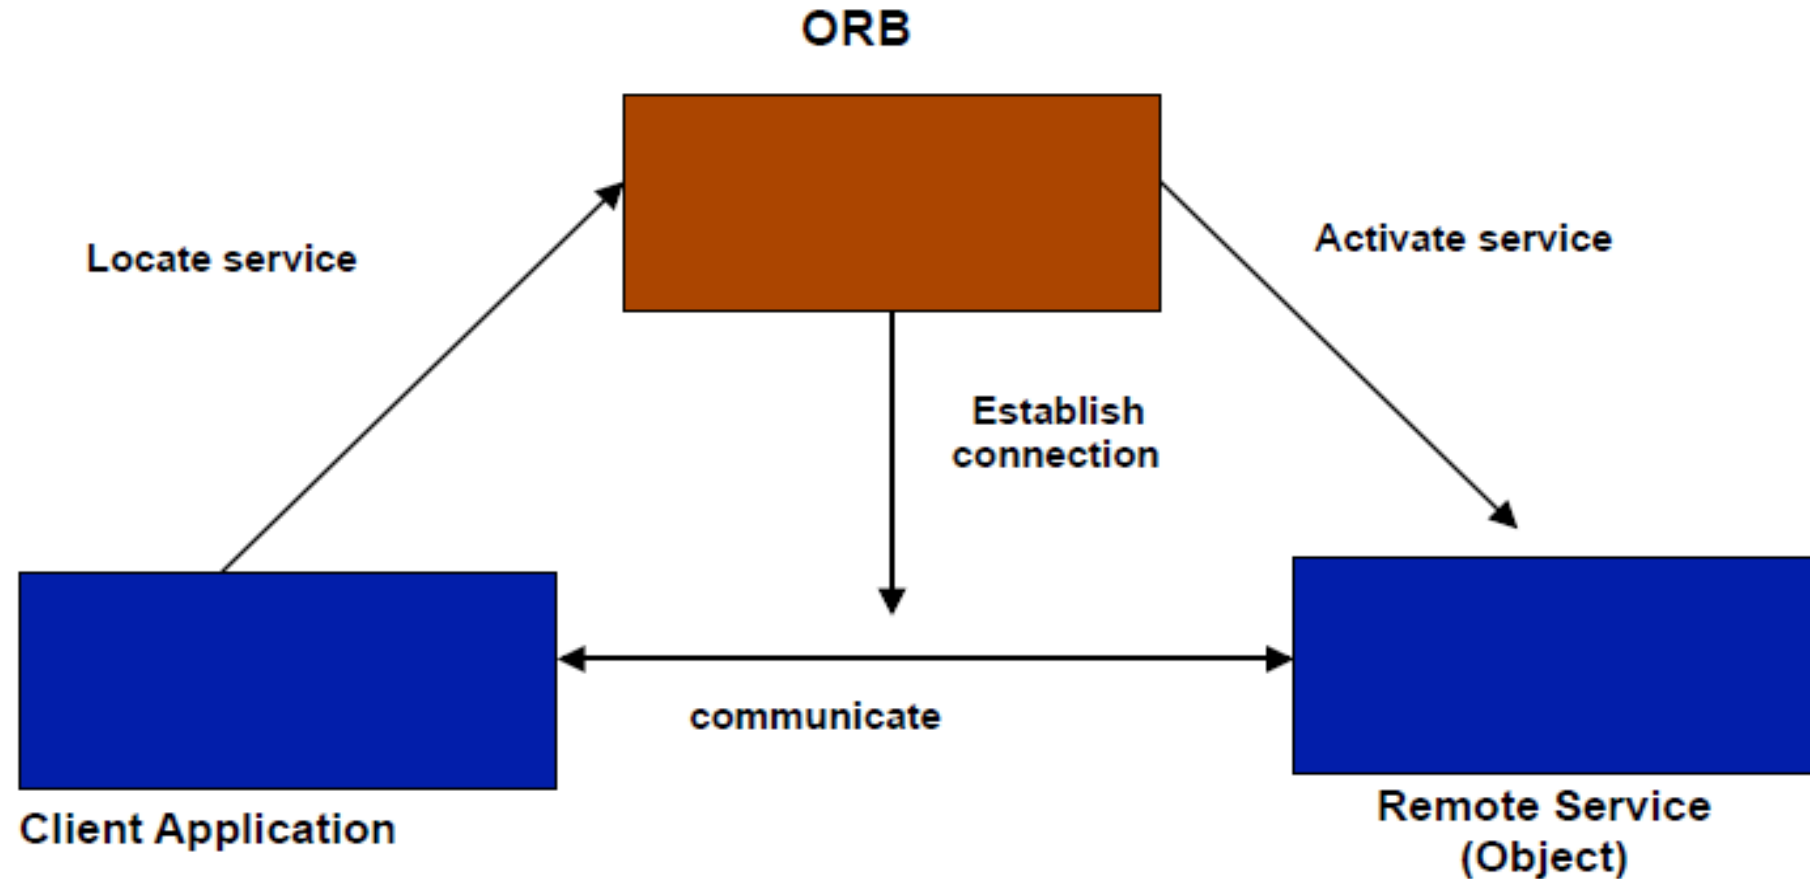

Properties of RPC

- Language-level pattern of **function call**
 - easy to understand for programmer
- **Synchronous** request/reply interaction
 - natural from a programming language point-of-view
 - matches replies to requests
 - built in synchronization of requests and replies
- **Distribution transparency (in the no-failure case)**
 - hides the complexity of a distributed system
- **Various reliability guarantees**
 - deals with some distributed systems aspects of failure

Disadvantages of RPC

- Synchronous request/reply interaction
 - tight coupling between client and server
 - client may block for a long time if server loaded
- Leads to multi-threaded programming at client
 - slow/failed clients may delay servers when replying
 - multi-threading essential at servers
- Distribution Transparency problem
 - Not possible to mask all problems
- RPC paradigm is not object-oriented
 - invoke functions on servers as opposed to methods on objects

Object Request Broker(ORB)

CORBA architecture

Main CORBA features

- Object request broker (ORB)
- OMG(Object Management Group) interface definition language(IDL)
- Language mapping
- Stub and skeletons
- Interface repository
- Dynamic invocation and dispatch
- Object adapters
- Inter ORB protocols

Object Request Broker (ORB)

- ORB is a **middleware application component** that uses the common object request broker architecture (CORBA) specification, **enabling developers to make application calls within a computer network.**
- ORB is an agent that transmits client/server operation invocations in a distributed environment and ensures transparent object communication.
- **Major functionality includes:**
 - **Interface definition**
 - **Location and activation of remote objects**
 - **Communication between clients and objects**

Object Oriented Middleware(OOM)

- **Objects** can be *local* or *remote*
- **Object references** can be *local* or *remote*
- Remote objects have visible **remote interfaces**
- Masks remote objects as being local using **proxy objects**
- **Remote method invocation**

Properties of OOM

- Support for object-oriented programming model
 - objects, methods, interfaces, encapsulation, ...
 - exceptions (were also in some RPC systems e.g. Mayflower)
- Synchronous request/reply interaction
 - same as RPC
- Location Transparency
 - system (ORB) maps object references to locations
- Services comprising multiple servers are easier to build with OOM
 - RPC programming is in terms of **server-interface (operation)**
 - RPC system looks up server address in a location service

CORBA

- **Common Object Request Broker Architecture**
 - Open standard by the OMG (Object Management Group)
 - Language and platform **independent**
- **Object Request Broker (ORB)**
 - General Inter-ORB Protocol (GIOP) for **communication**
 - Interoperable Object References (IOR) **contain object location**
 - **CORBA Interface Definition Language (IDL)**
- **Stubs (proxies) and skeletons created by IDL compiler**
 - Dynamic remote method invocation
- **Interface Repository**
 - Querying existing remote interfaces
- **Implementation Repository**
 - Activating remote objects on demand

CORBA Services (selection)

- Naming Service
 - Names -> remote object references
- Trading Service
 - Attributes (properties) -> remote object references
- Persistent Object Service
 - Implementation of persistent CORBA objects
- Transaction Service
 - Making object invocation part of transactions
- Event Service and Notification Service
 - In response to applications' need for asynchronous communication
 - built above synchronous communication with ***push*** or ***pull*** options
 - *not* an integrated programming model with general IDL messages

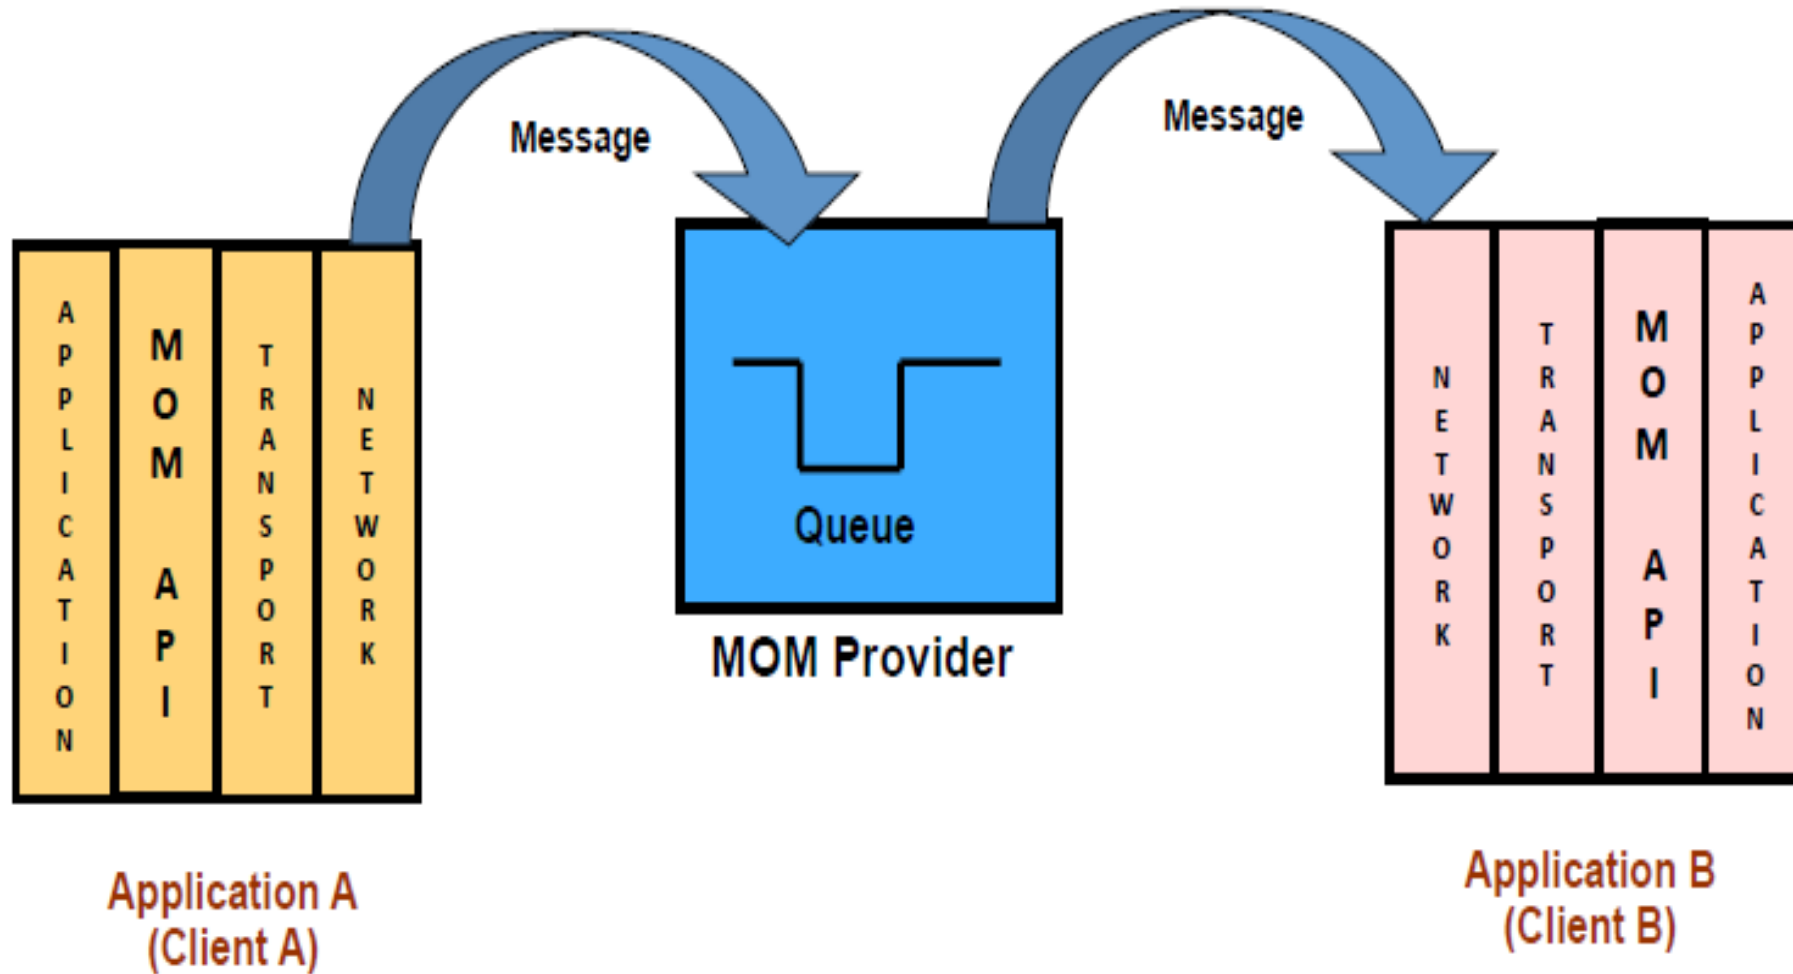

Disadvantages of OOM

- Synchronous request/reply interaction only
 - So CORBA **one way** semantics added and -
 - Asynchronous Method Invocation (AMI)
 - But *implementations* may not be loosely coupled
- Distributed garbage collection
 - Releasing memory for unused remote objects
- OOM rather static and heavy-weight
 - Bad for ubiquitous systems and embedded devices

Message Oriented Middleware(MOM)

- MOM (Message Oriented Middleware) is a client / server infrastructure which allows the application to be **distributed over multiple heterogeneous platforms**.
- Reduces complexity of applications spanning operating systems and network protocols by insulating them from un-necessary details.
- Data is exchanged by message passing and/or message queuing supporting **both synchronous and asynchronous** interactions between distributed computing processes.
- The MOM system ensures message delivery by using **reliable queues** and by providing the **directory, security, and administrative services** required to support messaging.

MOM - Demonstration

MOM - Advantages

- Asynchronous
- Flexible
- Portability
- Interoperability
- Reduces Complexity

Message-Oriented Middleware (MOM)

- Communication using **messages**
- Messages stored in **message queues**
- **message servers** decouple client and server
- Various assumptions about **message content**

Properties of MOM

- **Asynchronous interaction**
 - Client and server are **only loosely coupled**
 - Messages are queued
 - Good for application integration
- Support for **reliable delivery service**
 - Keep queues in persistent storage
- Processing of messages by intermediate message server(s)
 - May do filtering, transforming, logging, ...
 - Networks of message servers
- Natural for database integration

Java Message Service (JMS)

- API **specification** to access MOM implementations
- Two modes of operation *specified*:
 - **Point-to-point**
 - one-to-one communication using queues
 - **Publish/Subscribe**
 - Event-Based Middleware
- **JMS Server** implements JMS API
- JMS Clients connect to JMS servers
- Java objects can be serialized to JMS messages
- A JMS interface has been provided for message queue(MQ)
- pub/sub (one-to-many) - just a specification?

Web Services

- A web service is any piece of software that makes itself available over the internet and uses a standardized XML messaging system. XML is used to encode all communications to a web service
- Use well-known web standards for distributed computing
 - **Communication**
 - Message content expressed in **XML**
 - **Simple Object Access Protocol (SOAP)**
 - Lightweight protocol for sync/async. communication
 - **Service Description**
 - **Web Services Description Language (WSDL)**
 - Interface description for web services
 - **Service Discovery**
 - **Universal Description Discovery and Integration (UDDI)**
 - Directory with web service description in WSDL

Properties of Web Services

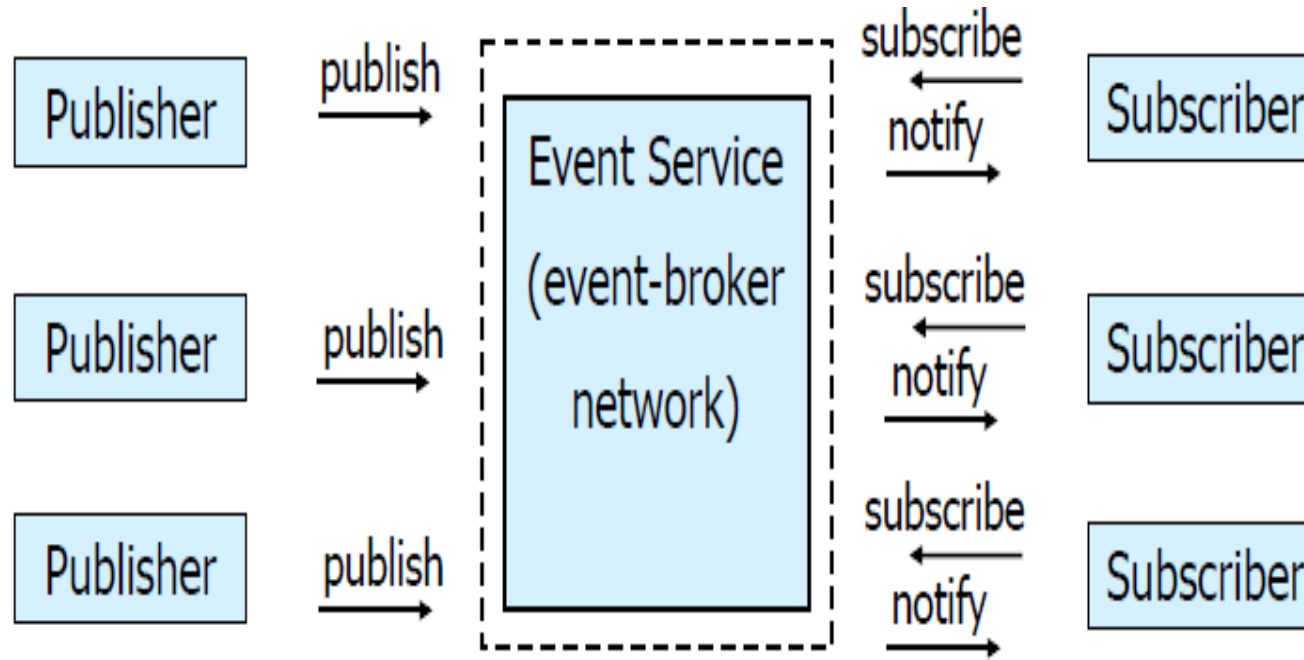

- Language-independent and open standard
- **SOAP** offers OOM and MOM-style communication:
 - Synchronous request/reply like OOM
 - Asynchronous messaging like MOM
 - Supports internet transports (http, smtp, ...)
 - Uses XML Schema for marshalling types to/from programming language types
- **WSDL** says how to use a web service
- **UDDI** helps to find the right web service
 - Exports SOAP API for access

Disadvantages of Web Services

- Low-level abstraction
 - leaves a lot to be implemented
- Interaction patterns have to be built
 - one-to-one and request-reply provided
 - one-to-many?
 - still synchronous service invocation, rather than notification
 - No nested/grouped invocations, transactions, ...
- No location transparency

Event-Based Middleware (Publish/Subscribe)

- **Publishers** (*advertise and*) *publish events* (messages)
- **Subscribers** express interest in events with *subscriptions*
- **Event Service** *notifies* interested subscribers of published events
- Events can have arbitrary content (typed) or name/value pairs

Properties of Publish/Subscribe

- Asynchronous communication
 - Publishers and subscribers are loosely coupled
- Many-to-many interaction between pubs. and subs.
 - Scalable scheme for large-scale systems
 - Publishers do not need to know subscribers, and vice-versa
 - Dynamic join and leave of pubs, subs
- (Topic and) Content-based pub/sub very expressive
 - Filtered information delivered only to interested parties
 - Efficient content-based routing through a broker network

COM/DCOM

- Component Object Model (COM)/Distributed Component Object Model(DCOM)
- Microsoft's middleware infrastructure in many ways similar to CORBA
- Defines a binary standard for component interoperability
- Programming language independence
- Platform independent
 - Windows (95, 98, NT)
 - Mac
 - Unix
- Distribution transparency
- Does exploit operational characteristics
- Dynamic component loading and unloading

DCOM

- DCOM = COM binary standard
 - +
 - runtime infrastructure for communicating across distributed address spaces initially only on Windows
- adding Mac and Unix
- Attempts to address challenges of distributed computing interacting components should be “close” to one another some components’ locations are fixed inverse relationship between component size and flexibility

.NET – What Is It?

- Software platform
- Language neutral
- In other words:
 - .NET is not a language (Runtime and a library for writing and executing written programs in any compliant language)
 - .NET is a new framework for developing web-based and windows-based applications within the Microsoft environment.
 - The framework offers a fundamental shift in Microsoft strategy: it moves application development from client-centric to server-centric.
 - Dramatically simplifies development and deployment
 - Supports multiple programming languages

.NET – What Is It?

.NET Framework Services

- Common Language Runtime
- Windows Forms
- ASP.NET
 - Web Forms
 - Web Services
- ADO.NET, evolution of ADO
- Visual Studio.NET

Note

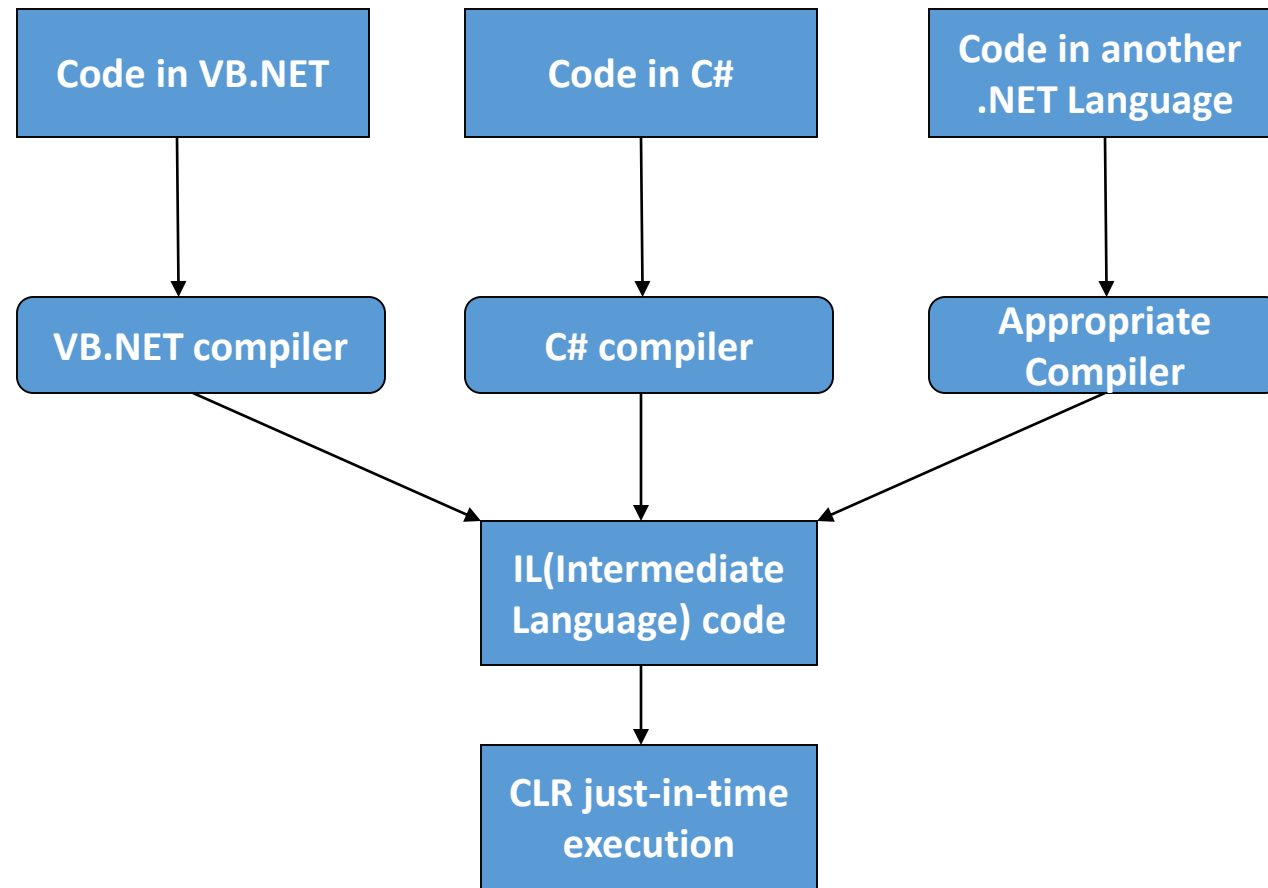

- Common Language Runtime
 - Common, secure execution environment.
 - We'll drill into this in some detail in the first parts of the presentation.
- Windows[®] forms
 - Framework for building rich clients
 - A demonstration will highlight some of these features, such as the delegate-based event model.
- ASP.NET
 - Web forms
 - Manageable code (non spaghetti)
 - Logical evolution of ASP (compiled)
 - Again, we'll drill into a hint at the power of Web Forms with a demonstration
 - Web Services
 - Programming the Internet to leverage the "power at the edge of the cloud".
 - We will cover this in detail, as this – along with the CLR – is one of the more powerful aspects of .NET Framework.
- ADO.NET, evolution of ADO
 - New objects (e.g., DataSets, Datareader)
- Visual Studio.NET
 - Most productive development environment gets better and fully supports the .NET Framework

Common Language Runtime (CLR)

- CLR works like a virtual machine in executing all languages.
- All .NET languages must obey the rules and standards imposed by CLR. Examples:
 - Object declaration, creation and use
 - Data types, language libraries
 - Error and exception handling
 - Interactive Development Environment (IDE)
- Development
 - Mixed language applications
 - Common Language Specification (CLS)
 - Common Type System (CTS)
 - Automatic memory management
 - Consistent error handling
- Deployment
 - Removal of registration dependency

- CTS is a rich type system built into the CLR
 - Implements various types (int, double, etc)
 - And operations on those types
- CLS is a set of specifications that language and library designers need to follow
 - This will ensure interoperability between languages
- CLR sits on top of OS to provide a *virtual environment* for hosting managed applications
 - What is CLR similar to in Java?
 - Java Virtual Machine (JVM)
- CLR loads modules containing executable and executes their code
- IL(Intermediate Language) instructions are just-in-time (JIT) compiled into native machine code at run time

Compilation in .NET

Intermediate Language (IL)

- .NET languages are **not compiled** to machine code.
- They are compiled to an Intermediate Language (IL).
- CLR accepts the IL code and recompiles it to machine code.
- The recompilation is just-in-time (JIT) meaning it is done as soon as a function or subroutine is called.
- The JIT code stays in memory for subsequent calls.
- In cases where there is not enough memory it is discarded thus making JIT process interpretive.

Languages

- Languages provided by MS
 - VB, C++, C#, J#, JScript
- Third-parties are building
 - APL, COBOL, Pascal, Eiffel, Haskell, ML, Oberon, Perl, Python, Scheme, Smalltalk...

Windows Forms

- Framework for Building Rich Clients
 - RAD (Rapid Application Development)
 - Rich set of controls
 - Data aware
 - Printing support
 - UI inheritance

Thank You !
